

Lamsa Platform Project Report

A concise overview of the marketplace, architecture, and current delivery state.

1. Project Overview

Lamsa is a multi-role artisan marketplace designed to connect Moroccan artisans with buyers through two main commerce experiences: direct product purchasing and live auction bidding. Buyers can browse products, view artisan stores, add items to cart, complete checkout, track orders, and place bids on live auctions. Artisans can manage their store, products, auctions, bids, and incoming orders through a dedicated workspace, while administrators oversee platform structure and marketplace governance.

2. Main User Roles and Platform Flows

Role	Main Responsibilities
Buyer	Browse products and stores, place bids, manage profile, complete checkout, and follow orders.
Artisan	Create a store, publish products and auctions, monitor bids, and fulfill orders from processing to delivery.
Admin	Manage artisans and categories, monitor dashboard activity, and keep the marketplace structure clean.

One important architectural detail is that a single buyer checkout can produce multiple artisan-specific orders. This keeps fulfillment separated per artisan while preserving one smooth customer checkout journey.

3. Technologies and Architecture

The application is built with Laravel as the backend framework, Blade and Tailwind CSS for the user interface, Vite for frontend asset bundling, and Spatie Permission for role and access control. The data model is organized around core entities such as User, Artisan, Store, Product, Auction, Bid, Order, and Review. The codebase follows an MVC structure and also uses service classes, form requests, policies, middleware, and enums to keep business logic separated and easier to maintain.

Examples of these architectural decisions include profile-completion middleware before checkout, policy-based bid authorization, an order checkout service to handle order batch creation, and dashboard services that prepare artisan statistics outside the controller layer.

4. Current Delivery Status

At the current stage, the project has a strong working MVP. Authentication, multi-role access, dynamic homepage sections, product browsing, cart and checkout flow, buyer account pages, auction browsing, bid placement, artisan dashboard operations, admin category management, and order fulfillment status transitions are all implemented. Automated feature tests are also in place to protect the core flows.

Two larger areas remain partially complete: a real payment gateway integration and a full end-of-auction lifecycle after bidding time expires. Even so, the platform is already in a stable state for demonstration, architectural study, and incremental improvement.

5. Conclusion

Lamsa is more than a simple e-commerce site. It combines marketplace management, artisan identity, live bidding, order orchestration, and role-based dashboards in one cohesive application. The project demonstrates practical Laravel architecture, real business flow modeling, and progressive improvement through testing and refactoring.

This makes it a strong student project for presenting full stack skills, clean backend structure, and marketplace domain understanding.

Note: This report was intentionally kept short at 1-2 pages for quick academic or presentation use.
